# SQL - Lab Assignment #1

## Introduction

In this lesson, we'll run through some practice questions to reinforce your knowledge of SQL queries.

## Objectives

You will be able to:

- Practice interpreting "word problems" and translating them into SQL queries
- Practice deciding and performing whichever type of `JOIN` is best for retrieving desired data
- Practice using `GROUP BY` statements in SQL to apply aggregate functions like `COUNT`, `MAX`, `MIN`, and `SUM`
- Practice using the `HAVING` clause to compare different aggregates
- Practice writing subqueries to decompose complex queries

## Your Task: Querying a Customer Database

shelves filled with colorful model cars

Photo by Karen Vardazaryan on Unsplash

### Business Understanding

Your employer makes miniature models of products such as classic cars, motorcycles, and planes. They want you to pull several reports on different segments of their past customers, in order to better understand past sales as well as determine which customers will receive promotional material.

### Data Understanding

You may remember this database from a previous lab. As a refresher, here's the ERD diagram for this database:

The queries you are asked to write will become more complex over the course of the lab.

## Getting Started

As in previous labs, we'll make use of the `sqlite3` library as well as `pandas`. By combining them, we'll be able to write queries as Python strings, then display the results in a conveniently-formatted table.

***Note:*** Throughout this lesson, the only thing you will need to change is the content of the strings containing SQL queries. You do NOT need to modify any of the code relating to `pandas`; this is just to help make the output more readable.

In the cell below, we:

- Import the necessary libraries, `pandas` and `sqlite3`
- Establish a connection to the database `data.sqlite`, called `conn`

```
# Run this cell without changes
import sqlite3
import pandas as pd

conn = sqlite3.Connection("data/data.sqlite")
```

The basic structure of a query in this lab is:

- Write the SQL query inside of the Python string
- Use `pd.read_sql` to display the results of the query in a formatted table

For example, if we wanted to select a list of all product lines from the company, that would look like this:

```
# Run this cell without changes
q0 = """
SELECT productline
FROM productlines
;
"""

pd.read_sql(q0, conn)

        productLine
0      Classic Cars
1       Motorcycles
2            Planes
3             Ships
4            Trains
5  Trucks and Buses
6      Vintage Cars
```

From now on, you will replace `None` within these Python strings with the actual SQL query code.

## Part 1: Basic Queries

First, let's review some basic SQL queries, which do not require any joining, aggregation, or subqueries.

## Query 1: Customers with Credit Over 25,000 in California

Write a query that gets the contact first name, contact last name, phone number, address line 1, and credit limit for all customers in California with a credit limit greater than 25000.00.

(California means that the `state` value is `'CA'`.)

### Expected Output

```
# Replace None with appropriate SQL code
q1 = """
SELECT contactFirstName
       ,contactLastName
       ,phone
       ,addressLine1
       ,creditLimit
FROM customers
WHERE state = 'CA'
    AND creditLimit > 25000
;
"""

q1_result = pd.read_sql(q1, conn)
q1_result

  contactFirstName contactLastName       phone
addressLine1  \

Ln.
8            Steve        Thompson  3105553722            3675 Furth
Circle
9              Sue          Taylor  4155554312            2793 Furth
Circle
```

```
   creditLimit
0       210500
1        64600
2        84600
3        90700
4       105000
5       105000
6        57700
7        77600
8        55400
9        60300
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q1_result.columns) == ['contactFirstName',
'contactLastName', 'phone', 'addressLine1', 'creditLimit']

# Testing how many rows are returned
assert len(q1_result) == 10

# Testing the values in the first result
assert list(q1_result.iloc[0]) == ['Susan', 'Nelson', '4155551450',
'5677 Strong St.', 210500]
```

## Query 2: Customers Outside of the USA with "Collect" in Their Name

Write a query that gets the customer name, state, and country, for all customers outside of the USA with `"Collect"` as part of their customer name.

We are looking for customers with names like `"Australian Collectors, Co."` or `"BG&E Collectables"`, where `country` is not `"USA"`.

Expected Output

```
# Replace None with appropriate SQL code
q2 = """
SELECT customerName
      ,state
      ,country
FROM customers
WHERE customerName LIKE '%Collect%'
      AND country != 'USA'
;
"""
```

```
q2_result = pd.read_sql(q2, conn)
q2_result
```

```
                           customerName     state      country
0           Australian Collectors, Co.  Victoria    Australia
1              Clover Collections, Co.      None      Ireland
2                UK Collectables, Ltd.      None           UK
3           King Kong Collectables, Co.      None    Hong Kong
4                 Heintze Collectables      None      Denmark
5     Royal Canadian Collectables, Ltd.        BC       Canada
6                    BG&E Collectables      None  Switzerland
7                   Reims Collectables      None       France
8                Precious Collectables      None  Switzerland
9                Salzburg Collectables      None      Austria
10              Tokyo Collectables, Ltd     Tokyo        Japan
11      Stuttgart Collectable Exchange      None      Germany
12  Bavarian Collectables Imports, Co.      None      Germany
13          Australian Collectables, Ltd  Victoria    Australia
14            Kremlin Collectables, Co.      None       Russia
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q2_result.columns) == ['customerName', 'state', 'country']

# Testing how many rows are returned
assert len(q2_result) == 15

# Testing the values in the first result
assert list(q2_result.iloc[0]) == ['Australian Collectors, Co.',
'Victoria', 'Australia']
```

## Query 3: Customers without Null States

Write a query that gets the full address (line 1, line 2, city, state, postal code, country) for all customers where the `state` field is not null.

Here we'll only display the first 10 results.

### Expected Output

```
# Replace None with appropriate SQL code
q3 = """
SELECT addressLine1
      ,addressLine2
      ,city
      ,state
      ,postalCode
      ,country
FROM customers
WHERE state IS NOT NULL
;
"""

q3_result = pd.read_sql(q3, conn)
q3_result.head(10)
```

```
                addressLine1 addressLine2           city     state
postalCode  \
0             8489 Strong St.                      Las Vegas        NV

97823
9              4658 Baden Av.                     Cambridge        MA
51247

     country
0        USA
1  Australia
2        USA
3        USA
4        USA
5        USA
6        USA
7        USA
8        USA
9        USA
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q3_result.columns) == ['addressLine1', 'addressLine2',
'city', 'state', 'postalCode', 'country']

# Testing how many rows are returned
assert len(q3_result) == 49

# Testing the values in the first result
assert list(q3_result.iloc[0]) == ['8489 Strong St.', '', 'Las Vegas',
'NV', '83030', 'USA']
```

You have now completed all of the basic queries!

## Part 2: Aggregate and Join Queries

### Query 4: Average Credit Limit by State in USA

Write a query that gets the average credit limit per state in the USA.

The two fields selected should be `state` and `average_credit_limit`, which is the average of the `creditLimit` field for that state.

Expected Output

```
# Replace None with appropriate SQL code
q4 = """
SELECT state
      ,AVG(creditLimit) AS average_credit_limit
FROM customers
WHERE country = 'USA'
GROUP BY state
;
"""

q4_result = pd.read_sql(q4, conn)
q4_result

  state  average_credit_limit
0    CA          83854.545455
1    CT          57350.000000
2    MA          70755.555556
3    NH         114200.000000
4    NJ          43000.000000
5    NV          71800.000000
6    NY          89966.666667
7    PA          84766.666667
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q4_result.columns) == ['state', 'average_credit_limit']

# Testing how many rows are returned
assert len(q4_result) == 8

# Testing the values in the first result
first_result_list = list(q4_result.iloc[0])
assert first_result_list[0] == 'CA'
assert round(first_result_list[1], 3) == round(83854.54545454546, 3)
```

## Query 5: Joining Customers and Orders

Write a query that uses `JOIN` statements to get the customer name, order number, and status for all orders. Refer to the ERD above to understand which tables contain these pieces of information, and the relationship between these tables.

We will only display the first 15 results.

### Expected Output

```
# Replace None with appropriate SQL code
q5 = """
SELECT c.customerName
      ,o.orderNumber
      ,o.status
FROM customers c
JOIN orders o ON c.customerNumber = o.customerNumber
;
"""
q5_result = pd.read_sql(q5, conn)
q5_result.head(15)
```

```
                  customerName  orderNumber     status
0            Atelier graphique        10123    Shipped
1            Atelier graphique        10298    Shipped
2            Atelier graphique        10345    Shipped
3           Signal Gift Stores        10124    Shipped
4           Signal Gift Stores        10278    Shipped
5           Signal Gift Stores        10346    Shipped
6   Australian Collectors, Co.        10120    Shipped
7   Australian Collectors, Co.        10125    Shipped
8   Australian Collectors, Co.        10223    Shipped
9   Australian Collectors, Co.        10342    Shipped
```

```
10  Australian Collectors, Co.        10347      Shipped
11            La Rochelle Gifts        10275      Shipped
12            La Rochelle Gifts        10315      Shipped
13            La Rochelle Gifts        10375      Shipped
14            La Rochelle Gifts        10425   In Process
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q5_result.columns) == ['customerName', 'orderNumber',
'status']

# Testing how many rows are returned
assert len(q5_result) == 326

# Testing the values in the first result
assert list(q5_result.iloc[0]) == ['Atelier graphique', 10123,
'Shipped']
```

## Query 6: Total Payments

Write a query that uses `JOIN` statements to get top 10 customers in terms of total payment amount. Find the customer name, customer number, and sum of all payments made. The results should be ordered by the sum of payments made, starting from the highest value.

The three columns selected should be `customerName`, `customerNumber` and `total_payment_amount`.

Expected Output

```
# Replace None with appropriate SQL code
q6 = """
SELECT c.customerName
      ,c.customerNumber
      ,SUM(p.amount) AS total_payment_amount
FROM customers c
JOIN payments p ON c.customerNumber = p.customerNumber
GROUP BY c.customerName
ORDER BY total_payment_amount DESC
LIMIT 10
;
"""
q6_result = pd.read_sql(q6, conn)
q6_result
```

```
                      customerName  customerNumber  total_payment_amount
0           Euro+ Shopping Channel             141             715738.98
1  Mini Gifts Distributors Ltd.                124             584188.24
2     Australian Collectors, Co.               114             180585.07
3                Muscle Machine Inc            151             177913.95
4          Dragon Souveniers, Ltd.             148             156251.03
5     Down Under Souveniers, Inc               323             154622.08
6                   AV Stores, Co.             187             148410.09
7         Anna's Decorations, Ltd              276             137034.22
8        Corporate Gift Ideas Co.              321             132340.78
9           Saveley & Henriot, Co.             146             130305.35
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q6_result.columns) == ['customerName', 'customerNumber',
'total_payment_amount']

# Testing how many rows are returned
assert len(q6_result) == 10

# Testing the values in the first result
assert list(q6_result.iloc[0]) == ['Euro+ Shopping Channel', 141,
715738.98]
```

## Query 7: Products that Have Been Purchased 10 or More Times

Write a query that, for each customer, finds all of the products that they have purchased 10 or more times cumulatively. For each record, return the customer name, customer number, product name, product code, and total number ordered. Sort the rows in ascending order by the quantity ordered.

The five columns selected should be `customerName`, `customerNumber`, `productName`, `productCode`, and `total_ordered`, where `total_ordered` is the sum of all quantities of that product ordered by that customer.

***Hint***: For this one, you'll need to make use of `HAVING`, `GROUP BY`, and `ORDER BY` — make sure you get the order of them correct!

### Expected Output

```
# Replace None with approprite SQL code
q7 = """
SELECT c.customerName
      ,c.customerNumber
      ,p.productName
      ,p.productCode
      ,SUM(od.quantityOrdered) AS total_ordered
FROM customers c
JOIN orders o ON c.customerNumber = o.customerNumber
JOIN orderdetails od ON o.orderNumber = od.orderNumber
JOIN products p ON od.productCode = p.productCode
GROUP BY c.customerNumber
        ,p.productName
        ,p.productCode
HAVING SUM(od.quantityOrdered) >= 10
ORDER BY total_ordered ASC
;
"""
q7_result = pd.read_sql(q7, conn)
q7_result
```

```
                       customerName  customerNumber  \
0                       Petit Auto             314
1     Extreme Desk Decorations, Ltd            412

2529  1958 Chevy Corvette Limited Edition    S24_2840            245
2530             1992 Ferrari 360 Spider red    S18_3232            308

[2531 rows x 5 columns]
```

The following code checks that your result is correct:

```
# Run this cell without changes
# Testing which columns are returned
assert list(q7_result.columns) == ['customerName', 'customerNumber',
'productName', 'productCode', 'total_ordered']

# Testing how many rows are returned
assert len(q7_result) == 2531

# Testing the values in the first result
assert list(q7_result.iloc[0]) == ['Petit Auto', 314, '1913 Ford Model
T Speedster', 'S18_2949', 10]
```

## Query 8: Employees in Offices with Fewer than Five Employees

Finally, get the first name, last name, employee number, and office code for employees from offices with fewer than 5 employees.

***Hint:*** Use a subquery to find the relevant offices.

Expected Output

```
# Replace None with approprite SQL code
q8 = """
SELECT e.lastName
      ,e.firstName
      ,e.employeeNumber
      ,e.officeCode
FROM employees e
WHERE e.officeCode IN(SELECT o.officeCode
                      FROM offices o
                      JOIN employees e2 ON o.officeCode =
e2.officeCode
                      GROUP BY o.officeCode
                      HAVING COUNT(e2.employeeNumber) < 5)
;
"""
q8_result = pd.read_sql(q8, conn)
q8_result
```

```
     lastName firstName  employeeNumber  officeCode
0   Patterson   William            1088           6
1    Firrelli     Julie            1188           2
2   Patterson     Steve            1216           2
3       Tseng  Foon Yue            1286           3
4     Vanauf    George            1323           3
5        Bott     Larry            1501           7
6       Jones     Barry            1504           7
7      Fixter      Andy            1611           6
8       Marsh     Peter            1612           6
```

```
9        King       Tom              1619          6
10      Nishi      Mami              1621          5
11       Kato   Yoshimi              1625          5
```

The following code checks that your result is correct:

```
# Run this cell without changes

# Testing which columns are returned
assert list(q8_result.columns) == ['lastName', 'firstName',
'employeeNumber', 'officeCode']

# Testing how many rows are returned
assert len(q8_result) == 12

# Testing the values in the first result
assert list(q8_result.iloc[0]) == ['Patterson', 'William', 1088, 6]
```

Now that we are finished writing queries, close the connection to the database:

```
# Run this cell without changes
conn.close()
```

## Summary

In this lesson, we produced several data queries for a model car company, mainly focused around its customer data. Along the way, we reviewed many of the major concepts and keywords associated with SQL `SELECT` queries: `FROM`, `WHERE`, `GROUP BY`, `HAVING`, `ORDER BY`, `JOIN`, `SUM`, `COUNT`, and `AVG`.
